Single factor experiments

Following data come from study investigating binding fraction for several antibiotics using n = 20 bovine serum samples:

Antibiotic		Binding F	ercentage		Sample mean	Sample s.d.
Penicillin G	29.6	24.3	28.5	32	28.6	3.2
Tetracyclin	27.3	32.6	30.8	34.8	31.4	3.2
Streptomycin	5.8	6.2	11	8.3	7.8	2.4
Erythromycin	21.6	17.4	18.3	19	19.1	1.8
Chloramphenicol	29.2	32.8	25	24.2	27.8	4.0

A ______ (CRD) was used.

(All assignment of antibiotics to serum samples equally likely.)

Q: Are the population means for these 5 treatments plausibly equal?

Q: Do these (sample) treatment means differ significantly?

```
Resident of bioding fractions by selfcides.
```

```

2
```

An ANOVA table. Note that df = 4.

Modelling the binding fraction expt

"Effects" model parameterizes antibiotic effects as differences from mean:

$$Y_{ij} = \mu + \tau_i + E_{ij}$$

for $i=1,\ldots,5$ and $j=1,\ldots,4$, where E_{ij} are i.i.d. $N(0,\sigma^2)$ errors.

- ullet μ overall population mean (avg of 5 treatment population means)
- ullet au_i difference between (population) mean for treatment i and μ
- \bullet σ^2 (population) variance of bf for a given antibiotic

To test H_0 : _____ = 0, we just carry out one-way ANOVA:

		Sum of	Mean		
Source	d.f.	squares	Square	F	p-value
Treatments	4	1481	370	41	,
Error	15	136	9		
Total	19	1617			

Conclusion? (Use F(0.05, 4, 15) = 3.06)

Parameter estimates $\hat{\mu}, \hat{\tau}_1, \hat{\tau}_2, \hat{\tau}_3, \hat{\tau}_4, \hat{\tau}_5$? Six parameters. Not uniquely estimable

$$\widehat{\mu + \tau_1} = \overline{y}_1$$
. = 28.6, ..., $\widehat{\mu + \tau_5} = \overline{y}_5$. = 27.8

Standard errors of parameter estimates?

$$StdErr(\overline{\mu} + \overline{\tau_i}) = StdErr(\overline{y}_i) =$$

Jason A. Osborne (N. C. State Univ.)

ST518 - Single

Table for balanced one-way ANOVA

 Y_{ij} denotes j^{th} observation receiving level i of treatment factor with t levels, for a total of N observations.

		Sum of	Mean	
Source	d.f.	squares	Square	F
Treatments	t-1	SS[T]	$MS[T] = \frac{SS[T]}{(t-1)}$	$F = \frac{MS[T]}{MS[E]}$
Error	N-t	SS[E]	$MS[E] = \frac{SS[E]}{(N-t)}$	
Total	N-1	SS[TOT]	(,, ,	

where

$$SS[T] = \sum \sum (\bar{y}_{i+} - \bar{y}_{..})^{2}$$

$$SS[E] = \sum \sum (y_{ij} - \bar{y}_{i+})^{2}$$

$$SS[TOT] = \sum \sum (y_{ij} - \bar{y}_{..})^{2}$$

The linear model $\mu_{ij} = E(Y_{ij}) = \mu + \tau_i$ could be fit using MLR with 5 **indicator** variables x_1, \ldots, x_5 for the 5 antibiotics. Let

$$x_{ij} = \begin{cases} 1 & \text{if treatment } j \\ 0 & \text{else} \end{cases}$$

A general linear model

Models which parameterize the effects of classification factors this way are general linear models. One-way ANOVA and linear regression models are general linear models. The linearity pertains to the parameters, not the explanatory variables.

Here, reparameterizing using 5-1 indicator variables leads to a general linear model. Define x_1, x_2, x_3, x_4 as before. Then the MLR model is

$$Y_i = \beta_0 + \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3} + \beta_4 x_{i4} + E_i$$
 $i = 1, \dots, 20$

where $E_i \stackrel{iid}{\sim} N(0, \sigma^2)$.

Remarks:

- $(X'X)^{-1}$ exists
- continuously valued covariates (as opposed to indicators) can be added and it is still a general linear model

For the one-way ANOVA,

$$\hat{\beta} = (X'X)^{-1}X'Y = \begin{pmatrix} 27.8 \\ 0.8 \\ 3.6 \\ -20.0 \\ -8.7 \end{pmatrix}$$

Estimates for the five treatment means obtained by substitution of $\hat{\beta}$ into $\mu(x_1, x_2, x_3, x_4) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_4$

(Compare with slide 1.)

For standard errors, use $\hat{\Sigma}$:

$$\hat{\Sigma} = MS[E](X'X)^{-1} = \begin{pmatrix} 2.26 & -2.26 & -2.26 & -2.26 & -2.26 \\ 4.53 & 2.26 & 2.26 & 2.26 \\ 4.53 & 2.26 & 2.26 & 2.26 \\ 4.53 & 2.26 & 4.53 & 2.26 \\ & & 4.53 & 2.26 & 4.53 \end{pmatrix}$$

Let a, b, c, d be defined by

$$a' = (1, 1, 0, 0, 0), b' = (1, 0, 1, 0, 0), c' = (1, 0, 0, 1, 0), d' = (1, 0, 0, 0, 1).$$

Then

$$\begin{array}{llll} \hat{\mu}(1,0,0,0) & = & \hat{\beta}_0 + \hat{\beta}_1 & = & a'\hat{\beta} \\ \hat{\mu}(0,1,0,0) & = & \hat{\beta}_0 + \hat{\beta}_2 & = & b'\hat{\beta} \\ \hat{\mu}(0,0,1,0) & = & \hat{\beta}_0 + \hat{\beta}_3 & = & c'\hat{\beta} \\ \hat{\mu}(0,0,0,1) & = & \hat{\beta}_0 + \hat{\beta}_4 & = & d'\hat{\beta} \\ \hat{\mu}(0,0,0,0) & = & \hat{\beta}_0 & = & \hat{\beta}_0 \end{array}$$

and

$$a'\hat{\Sigma}a=b'\hat{\Sigma}b=c'\hat{\Sigma}c=d'\hat{\Sigma}d=\hat{\Sigma}_{11}=2.3=\widehat{\text{Var}}(\hat{\beta}_0)=\widehat{\text{Var}}(\hat{\beta}_0+\hat{\beta}_j)$$
 so the estimated SE for any sample treatment mean is $\sqrt{2.3}=1.5$.

Checking matrix arithmetic:

$$(1,1,0,0,0)\widehat{\Sigma}\begin{pmatrix}1\\1\\0\\0\\0\end{pmatrix} = \\ = (1,1,0,0,0)\begin{pmatrix}2.26 & -2.26 & -2.26 & -2.26 & -2.26\\4.53 & 2.26 & 2.26 & 2.26\\4.53 & 2.26 & 2.26\\4.53 & 2.26 & 2.26\\4.53 & 2.26 & 4.53\end{pmatrix}\begin{pmatrix}1\\1\\0\\0\\0\end{pmatrix} = (0,2.26,0,0,0)\begin{pmatrix}1\\1\\0\\0\\0\end{pmatrix} = \\ = 2.26$$

$$\widehat{SE}(\widehat{\beta}_0 + \widehat{\beta}_1) = \sqrt{2.26} = 1.5 = \sqrt{MS(E)/4}$$

(Same for all sample treatment means in balanced experiment.)

A generalized inverse, of a matrix A, A^- has this property: $AA^-A = A$.

$$(X'X)^{-}X'Y = \left(\begin{array}{ccccc} 0.25 & -0.25 & -0.25 & -0.25 & 0 \\ -0.25 & 0.5 & 0.25 & 0.25 & 0.25 & 0 \\ -0.25 & 0.25 & 0.5 & 0.25 & 0.25 & 0 \\ -0.25 & 0.25 & 0.25 & 0.5 & 0.25 & 0 \\ -0.25 & 0.25 & 0.25 & 0.25 & 0.5 & 0.5 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{array} \right) \left(\begin{array}{c} 458.7 \\ 114.4 \\ 125.5 \\ 31.3 \\ 76.3 \\ 111.2 \end{array} \right) = \left(\begin{array}{c} 27.800 \\ 0.800 \\ 3.575 \\ -19.975 \\ -8.725 \\ 0 \end{array} \right)$$

$$= \begin{pmatrix} \widehat{\mu + \tau_5} \\ \widehat{\tau_1 - \tau_5} \\ \widehat{\tau_2 - \tau_5} \\ \widehat{\tau_3 - \tau_5} \\ \widehat{\tau_4 - \tau_5} \end{pmatrix}$$

The $\widehat{\tau}_i$ are not uniquely estimable, and will change with different choices for the generalized inverse, $(X'X)^-$, but $\widehat{\mu+\tau_i}$ (and many other functions of interest), are uniquely estimable, and will not change with different generalized inverses.

As an exercise, obtain the least squares estimate of $\mu+\tau_1$ and $\theta_2=\tau_2-\tau_1$ using each generalized inverse:

Gen'd Inverse	$\widehat{\mu+ au_1}$	$\widehat{ au_2- au_1}$
1	27.8 + 0.8 = 28.6	3.575 - 0.8 = 2.775
2	28.6 + 0 = 28.6	2.775 - 0.0 = 2.775
3	31.375 - 2.775 = 28.6	0 - (-2.775) = 2.775
4		
5		
6		

Apparently, μ, τ_1, \ldots are not uniquely estimable, but $\mu + \tau_1$ and $\tau_2 - \tau_1$ are.

Complete this table as an exercise.

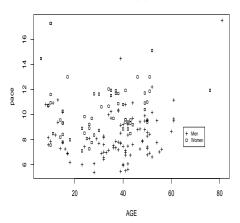

Estimable functions of regression coefficients

- <u>Definition</u>: In the general linear model, $Y = X\beta + E$, a linear combination of parameters, $\lambda'\beta$ is said to be _______ if there exists a linear combination of the data, a'Y with that as its expectation, so that $E(a'Y) = \lambda'\beta$. If no such linear combination exists, $\lambda'\beta$ is nonestimable.
- If $\lambda \in \text{rowsp}(X)$ then $\lambda'\beta$ is estimable. (λ can be obtained as a linear combination of the rows of X.)
- Is $\lambda'\beta$ estimable where $\lambda'=(1,1,0,0,0,0)$. Which rows of X?
- **②** Is $\lambda'\beta$ estimable where $\lambda' = (0, -1, 1, 0, 0, 0)$ Which rows of X?
- **3** Is $\lambda'\beta$ estimable where $\lambda' = (0, 1, 0, 0, 0, 0)$ Which rows of X?

A general linear model

Both indicator variables for factorial effects (sex) as well as continously valued variables (age, age squared).

Resolution Run (5k), 1/1/2004

Quadratic model $\mu(x) = \beta_0 + \beta_1 x + \beta_1 x^2$ used for association between mean pace and age. How could the model be extended to incorporate sex differences? Let $x_2 = x^2$ and let an indicator variable x_3 be defined by

$$x_3 = \begin{cases} 1 & \text{female} \\ 0 & \text{male} \end{cases}$$

Some candidate models:

$$\begin{array}{lll} \mu(x_1,x_2,x_3) & = & \beta_0 \\ \mu(x_1,x_2,x_3) & = & \beta_0+\beta_3x_3 \\ \mu(x_1,x_2,x_3) & = & \beta_0+\beta_1x_1 \\ \mu(x_1,x_2,x_3) & = & \beta_0+\beta_1x_1+\beta_2x_2 \\ \mu(x_1,x_2,x_3) & = & \beta_0+\beta_1x_1+\beta_2x_2+\beta_3x_3 \\ \mu(x_1,x_2,x_3) & = & \beta_0+\beta_1x_1+\beta_2x_2+\beta_3x_3+\beta_4\underbrace{x_1x_3}_{x_4}+\beta_5\underbrace{x_2x_3}_{x_5} \end{array}$$

```

Model 5

Comparison of models 5 and 6

reduced:
$$\mu(x_1, x_2, x_3) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3$$

full: $\mu(x_1, x_2, x_3) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_3 + \beta_4 x_1 x_3 + \beta_5 x_2 x_3$

Extra sum of squares:

$$R(\beta_4, \beta_5|\beta_0, \beta_1, \beta_2, \frac{\beta_3}{3}) = SS[R]_f - SS[R]_r = 293.5 - 290.3 = 3.0$$

The *F*-ratio

$$F = \frac{R(\beta_4, \beta_5 | \beta_0, \beta_1, \beta_2, \beta_3)/(5-3)}{MS[E]_f} = \frac{3.2/2}{3.21} = \frac{1.6}{3.21} = 0.5$$

The observed *F*-ratio is not significant on df = 2,154.

In SAS, you could use

```
proc reg;
  model pace=age age2 sexf agef age2f;
  test agef=0, age2f=0;
run;
```

to get the following model selection F-ratio in the output:

The REG Procedure Model: MODEL6

Nonlinear functions of parameters

Estimate "peak" running age for men/women. θ_M and θ_W denote peak running ages for men and women respectively. Using calculus on the model 6 regression,

$$\theta_{M} = -----$$
, $\theta_{W} = -----$

These are nonlinear functions of regression parameters. Note that acceptance of any model but 6 implies equality of these peak ages.

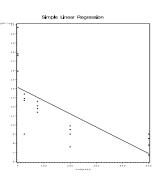

$$\hat{\theta}_W = \begin{cases} 30.5 & \text{different intercepts model (5)} \\ 30.1 & \text{full model (6)} \end{cases}$$

$$\hat{\theta}_{M} = \begin{cases} 30.5 & \text{different intercepts model (5)} \\ 31.1 & \text{full model (6)} \end{cases}$$

Lack-of-fit of a polynomial regression model

Completely randomized experiment in White Mountains of NH. n=20 lanes of dimension $0.5m \times 1.5m$ randomized to 5 foot-traffic treatments:

i : trt grp	x: # of passes	y _{ij} : Height(cm)			
1	0	20.7	15.9	17.8	17.6
2	25	12.9	13.4	12.7	9.0
3	75	11.8	12.6	11.4	12.1
4	200	7.6	9.5	9.9	9.0
5	500	7.8	9.0	8.5	6.7

Two models for mean plant height:

SLR model :
$$\mu(x) = \beta_0 + \beta_1 x_i$$

one-factor ANOVA model : $\mu_{ij} = \mu + \tau_i$

```
proc reg data=one;
  model y=numpass;

proc glm data=one;     *find the F-ratio that compares SLR with one-factor model;
  class cnumpass;     *find SS(Trt);
  model y=numpass cnumpass;     run;
```

When t treatments have interval scale, the SLR model, and all polynomials of degree $p \le t-2$, are nested in one-factor ANOVA model with t treatment means. F-ratio for lack-of-fit

To test for lack-of-fit of a polynomial (reduced) model of degree p, use extra sum-of-squares F-ratio on t-1-p and $N-t\ df$:

$$F = rac{SS[ext{lack of fit}]/(t-1-p)}{MS[ext{pure error}]}, \quad ext{where}$$

$$MS[pure error] = MS[E]_{full}$$
 and

$$SS[lack-of-fit] = SS[Trt] - SS[R]_{poly} = SS[E]_{poly} - SS[E]_{full}$$

= $SS[E]_{poly} - SS[pure error]$

In a simple linear (p = 1) model for the meadows data,

$$SS[lack of fit] = 243.163 - 141.295 = 101.867 \text{ on } t - 1 - p = 3df$$

and the sum of squares for pure error is $SS[E]_{full} = 30.93$ yielding

$$F = \frac{101.867/3}{30.93/15} \approx \frac{34}{2.1} = 16.5.$$

(highly significant since F(0.01, 3, 15) = 5.42.)

 \implies model misspecified: SLR model suffers from lack of fit.

Some terminology for factorial experiments:

- contrasts
- orthogonal contrasts
- multiple contrasts
- expected mean squares
- familywise or experimentwise error rates
- power

Comparisons (contrasts) among means

<u>Definition</u>: In the one-way ANOVA layout:

$$Y_{ij} = \mu_i + E_{ij}, i = 1, 2, \dots, t, \text{ and } j = 1, 2, \dots, n_i$$

with $E_{ij} \stackrel{iid}{\sim} N(0, \sigma^2)$, A linear combination of treatment means, $\theta = \sum c_i \mu_i$ is called a ______ if .

$$c_1 + c_2 + \cdots + c_t = \sum_{1}^{t} c_j = 0.$$

<u>Definition</u>: Contrasts in which only two of the coefficients are nonzero are called simple or _____ contrasts. Example: ____

<u>Definition</u>: Contrasts in with more than two nonzero coefficients are called _____ contrasts. Example: _____

Result: The *best* estimator for a contrast of interest obtained by substituting treatment group sample means \bar{y}_{i+} for treatment population means μ_i in the contrast θ :

$$\hat{\theta} = c_1 \bar{Y}_{1+} + c_2 \bar{Y}_{2+} + \dots + c_t \bar{Y}_{t+}.$$

For binding fractions, contrast penicillin and Tetracyclin (population) means

$$\theta = \mu_1 - \mu_2 = (1)\mu_1 + (-1)\mu_2 + (0)\mu_3 + (0)\mu_4 + (0)\mu_5$$

Using the <u>result</u>, point estimator of θ is

$$\hat{\theta} = \hat{\mu}_1 - \hat{\mu}_2 = \bar{Y}_{1+} - \bar{Y}_{2+}$$

	Binding				Sample	Sample
Antibiotic		Perce	ntage	mean	variance	
Penicillin G	29.6	24.3	28.5	32	28.6	10.4
Tetracyclin	27.3	32.6	30.8	34.8	31.4	10.1
Streptomycin	5.8	6.2	11	8.3	7.8	5.7
Erythromycin	21.6	17.4	18.3	19	19.1	3.3
Chloramphenicol	29.2	32.8	25	24.2	27.8	15.9

		Sum of	Mean	
Source	d.f.	squares	Square	F
Treatments	4	1481	370	41
Error	15	136	9.05	
Total	19	1617		

Substitution of \bar{y}_{1+} and \bar{y}_{2+} yields $\hat{\theta}=28.6-31.4=-2.8.$

Q: How good is this estimate? (Quantify the associated uncertainty.)

Sampling distribution of $\hat{\theta}$

 $\widehat{ heta}$ a linear combo of independent averages of normals, hence normal with std.err.

$$SE(\hat{\theta}) = \sqrt{\frac{c_1^2}{n_1}\sigma^2 + \frac{c_2^2}{n_2}\sigma^2 + \dots + \frac{c_t^2}{n_t}\sigma^2} = \sqrt{\sigma^2 \sum_{i=1}^{i=t} \frac{c_i^2}{n_i}},$$

estimated by

$$\hat{SE}(\hat{\theta}) = \sqrt{MS[E] \sum_{i=1}^{i=t} \frac{c_i^2}{n_i}}$$

To test $H_0: \theta = \theta_0$ (often 0) versus $H_1: \theta \neq \theta_0$ a t use t-test:

$$t = rac{\mathsf{est} - \mathsf{null}}{\hat{SE}} = rac{\hat{ heta} - heta_0}{\hat{SE}(\hat{ heta})} \stackrel{H_0}{\sim} t_{N-t}.$$

At level α , the critical value for this test is $t(N-t, \alpha/2)$.

 $100(1-\alpha)\%$ confidence interval for a contrast $\theta = \sum c_i \mu_i$ given by

$$\pm t(\alpha/2, N-t)\sqrt{MS(E)}$$

Here,

$$\widehat{SE}(\hat{\theta}) = \sqrt{\left(\frac{1^2}{n_1} + \frac{(-1)^2}{n_2}\right)(9.05)} = \sqrt{\frac{9.05}{2}} = 2.127$$

So that the t statistic becomes

$$\frac{-2.8}{2.127} = -1.32$$

which is not in the critical region, so that the sample mean binding fractions for Penicillin G and Tetracyclin do not differ significantly.

A 95% confidence interval is given by

$$-2.8 \pm 2.13 (2.127)$$
 or $(-7.3, 1.7)$

Code (next page) estimates all pairwise contrasts involving Pen. G:

•
$$\theta_1 = a'\mu = (1, -1, 0, 0, 0)\mu$$

•
$$\theta_3 = c' \mu = ?$$

•
$$\theta_2 = b'\mu = ?$$

•
$$\theta_4 = d'\mu = ?$$

along with complex contrast comparing Pen G. with mean of other four antibiotics:

$$\theta_5 = ($$
 , , , ,) μ

Here $\mu = (\mu_1, \mu_2, \mu_3, \mu_4, \mu_5)'$.

Orthogonal contrasts: Let two contrasts θ_1 and θ_2 be given by

$$heta_1 = c_1 \mu_1 + \dots + c_t \mu_t$$
 and $heta_2 = d_1 \mu_1 + \dots + d_t \mu_t$

<u>Definition</u>: The two contrasts θ_1 and θ_2 are <u>mutually orthogonal</u> if the products of their coefficients sum to zero: $c_1d_1+\cdots c_td_t=\sum_{i=1}^t c_id_i=0$. A *set* of several contrasts θ_1,\ldots,θ_k is mutually orthogonal if all pairs mutually orthogonal.

$$(-1,1,0,0,0)$$
 and $(0,0,-1,1,0)$ orthogonal ?
$$(1,-1/2,-1/2,0,0) \text{ and } (0,0,0,-1,1) \text{ orthogonal ?} \\ (-1,1,0,0,0) \text{ and } (0,-1,1,0,0) \text{ orthogonal ?}$$

 θ_i and θ_j orthogonal $\Longrightarrow \hat{\theta}_i$ and $\hat{\theta}_j$ are statistically independent.

Contrast sums of squares

As SS[Trt] quantifies treatment effect, $\overline{SS(\theta_i)}$ quantifies contrast effect:

$$SS[\hat{\theta}_1] = \frac{\hat{\theta}_1^2}{\left(\frac{c_1^2}{n_1} + \dots + \frac{c_t^2}{n_t}\right)}$$

If $\theta_1,\ldots,\theta_{t-1}$ are t-1 mutually orthogonal contrasts, then

$$SS[Trt] = SS(\hat{\theta}_1) + SS(\hat{\theta}_2) + \cdots + SS(\hat{\theta}_{t-1})$$

For single df contrasts, if $H_0: \theta_i = 0$,

$$E(SS[\hat{\theta}_j]) = \sigma^2.$$

To test $H_0: \theta_j = 0$ versus $H_1: \theta_j \neq 0$, use F below, with $df = \underline{\hspace{1cm}}, \underline{\hspace{1cm}}$

$$F = \frac{SS[\hat{\theta}_j]}{MS[E]}$$

For $\theta_1 = \mu_1 - \mu_2$ in the binding fractions,

$$F = \frac{(-2.8)^2}{MS[E]\left(\frac{1}{4} + \frac{(-1)^2}{4} + 0 + 0 + 0\right)} = 1.73.$$

(Using F(0.05, 1, 15) = 4.54, is $H_0: \theta_1 = 0$ plausible?)

Consider the following 2 contrasts:

$$\theta_1 = \mu_{M} - \mu_{A}$$
 and $\theta_2 = \mu_{C} - \frac{\mu_{M} + \mu_{A}}{2}$

Q: Are these contrasts orthogonal?

Q: Are the estimated contrasts $\hat{\theta}_1$ and $\hat{\theta}_2$ independent?

Exercise: Compute $SS[\hat{\theta}_1]$ and $SS[\hat{\theta}_2]$. Add em up.

Multiple Comparisons

- Too many tests of significance brings creeping type I error rate
- e.g. consider the case with t=5 (antibiotic treatments): all simple (pairwise) contrasts of the form $\theta=\mu_i-\mu_j$
- ullet $\left(egin{array}{c} 5 \\ 2 \end{array} \right) =$ ______ tests of significance each at level lpha = 0.05

When testing \emph{k} contrasts, the experimentwise error rate (or familywise) is

$$fwe = Pr($$

Methods for simultaneous inference for multiple contrasts include

- Bonferroni
- Tukey
- Scheffé (won't cover)

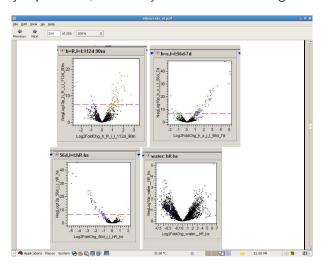

When the number of comparisons is in the thousands, and FWE control is hopeless, more manageable type I error rate is the False Discovery Rate (FDR):

$$FDR = E\left(\frac{\text{Falsely rejected null hypotheses}}{\text{Number of rejected null hypotheses}}\right)$$

See qvalue() in R and

http://www4.stat.ncsu.edu/~jaosborn/research/microarray/software/qvalues.sas

A context in which multiplicity is a big issue: Microarray experiments, which may involve thousands of genes and tests

(Data courtesy of Cassi Myburg)

Bonferroni

Consider k contrasts of interest. Bonferroni adjustment to α which controls *fwe* is

$$\alpha' = \frac{\alpha}{k}$$

Simultaneous 95% confidence intervals for the k contrasts given by

$$a_1 \bar{Y}_{1+} + a_2 \bar{Y}_{2+} + \cdots + a_t \bar{Y}_{t+} \pm t(\frac{\alpha'}{2}, \nu) \sqrt{MS[E] \sum \frac{a_j^2}{n_j}}$$

and

$$b_1 \bar{Y}_{1+} + b_2 \bar{Y}_{2+} + \dots + b_t \bar{Y}_{t+} \pm t(\frac{\alpha'}{2}, \nu) \sqrt{MS[E]} \sum_{j=1}^{n_j} \frac{b_j^2}{n_j}$$

$$k_1 \bar{Y}_{1+} + k_2 \bar{Y}_{2+} + \cdots + k_t \bar{Y}_{t+} \pm t(\frac{\alpha'}{2}, \nu) \sqrt{MS[E] \sum \frac{k_j^2}{n_j}}$$

where ν denotes df for error. $t(\frac{\alpha'}{2}, \nu)$ might have to be obtained using software.

For the binding fraction example, consider only pairwise comparisons with Penicillin:

$$\theta_1 = \mu_1 - \mu_2, \theta_2 = \mu_1 - \mu_3, \theta_3 = \mu_1 - \mu_4, \theta_4 = \mu_1 - \mu_5$$

We have k = 4, $\alpha' = 0.05/k = 0.0125$, and $t(\frac{\alpha'}{2}, 15) = \underline{\hspace{1cm}}$

Substitution leads to

$$t(\alpha', 15)\sqrt{MS[E]\left(\frac{(-1)^2}{4} + \frac{(-1)^2}{4} + \frac{0^2}{4} + \cdots + \frac{0^2}{4}\right)} = 2.84\sqrt{(9.05)\frac{2}{4}} = 6.0$$

so that simultaneous 95% confidence intervals for $\theta_1, \theta_2, \theta_3, \theta_4$ take the form

$$\bar{y}_1 - \bar{y}_i \pm 6.0$$

(actually simultaneous 95% confidence intervals)

Tukey

Tukey's method better than Scheffé 's method for all pairwise comparisons in balanced designs Is conservative, controlling experimentwise error rate, and has lower type II error rate in these cases than Scheffé . (More powerful.)

For simple contrasts of the form

$$\theta = \mu_j - \mu_k$$

to test

$$H_0: \theta = 0 \text{ vs } H_1: \theta \neq 0$$

reject H_0 at level α if

$$|\hat{\theta}| > q(t, N - t, \alpha) \sqrt{\frac{MS[E]}{n}}$$

where $q(t, N-t, \alpha)$ denotes α level studentized range for t means and N-t degrees of freedom. These studentized ranges can be found in Table C.11 of Rao.

For the IV data, q(3,15,0.05)=3.67. Tukey's 95% honestly significant difference (HSD) for pairwise comparisons of treatment means in this balanced design are

$$3.67\sqrt{\frac{MS(E)}{n}} = \underline{} = \underline{}$$

```
proc glm;
   class firm;
   model con=firm;
   means firm/scheffe tukey;
run;
```

```
Tukey's Studentized Range (HSD) Test for con
NOTE: This test controls the Type I experimentwise error rate, but it
         generally has a higher Type II error rate than REGWQ.

(Scheffé excluded)

Expected mean squares

 $\underline{\text{Definition}} \colon \mathsf{The} \ \boxed{\mathsf{treatment mean square}} \ \mathsf{is given by}$

$$MS[Trt] = \frac{SS[Trt]}{t-1} = \frac{1}{t-1} \sum_{i} \sum_{j} (\bar{y}_{i+} - \bar{y}_{..})^2$$

$$(\bar{y}_{\cdot\cdot} = \overline{y}_{++} \text{ and } \bar{y}_{i+} = \frac{1}{n_i} \sum_{i=1}^{n_i} y_{ij})$$

$$E[MS[Trt]; H_1] = E[SS[Trt]/(t-1); H_1]$$

$$= \sigma^2 + \frac{1}{t-1} \sum_i n_i (\mu_i - \mu)^2$$

$$= \sigma^2 + n \frac{1}{t-1} \sum_i (\mu_i - \mu)^2 \text{ (balanced case)}$$

$$= \sigma^2 + n \psi_T^2$$

where
$$\psi_T^2 = \frac{1}{t-1} \sum (\mu_i - \mu)^2$$
.

Note that under H_0 : $\mu_i \equiv \mu$ and $\psi_T^2 = 0$ so that

$$E[MS[Trt]; H_0] = E[SS[Trt]/(t-1); H_0] =$$

 $MS[E] = \frac{SS[E]}{N-t}$, (generalization of pooled variance S_p^2 to t > 2 groups):

$$MS[E] = \frac{SS[E]}{N-t} = \frac{1}{N-t} \sum_{i=1}^{i=t} \sum_{j=1}^{j=n_i} (y_{ij} - \bar{y}_{i+})^2$$

$$= \frac{1}{N-t} \sum_{i=1}^{t} (n_i - 1) s_i^2$$

$$= \left(\frac{n_1 - 1}{N-t}\right) s_1^2 + \left(\frac{n_2 - 1}{N-t}\right) s_2^2 + \dots + \left(\frac{n_t - 1}{N-t}\right) s_t^2$$

$$= "S_p^{2"}$$

Since $E(S_i^2) = \sigma^2$, MS[E] is unbiased for σ^2 regardless of H_0 or H_1 :

$$E(S_i^2) = \sigma^2 \Longrightarrow$$

$$E[MS[E]] = \left(\frac{n_1 - 1}{N - t}\right)\sigma^2 + \left(\frac{n_2 - 1}{N - t}\right)\sigma^2 + \dots + \left(\frac{n_t - 1}{N - t}\right)\sigma^2$$

$$= \sigma^2$$

$$E[MS[E]] = \sigma^2$$

Sample size computations for one-way ANOVA

Consider designing a completely randomized experiment that will have significance level α , power $1-\beta$, and sample size n to accept or reject the following hypotheses regarding the means of a response variable, Y with error variance σ^2 :

$$H_0: \mu_1 = \cdots = \mu_t$$
 vs $H_a: \psi_T^2 = \frac{1}{t-1} \sum (\mu_i - \mu)^2$.

Linear model, i.i.d. normal errors \rightarrow can calculate any one quantity given others. With H_0 true, F = MS(Trt)/MS(E) follows an F-distribution under With H_a true, F = MS(Trt)/MS(E) follows a non-central F-distribution with non-centrality parameter given below $(\tau_i = \mu_i - \overline{\mu})$:

$$\gamma =$$

• Suppose $t=4, n=9(N=36), \sigma^2=9, \alpha=.05$ and the hypotheses are

$$H_0: \mu_1 = \cdots = \mu_4$$
 vs $H_a: \mu_1 = \mu_2 = 9, \mu_3 = 10, \mu_4 = 12.$

Calculate the power, $P(\text{reject } H_0|H_a\text{true})$. (an area under non-central F density).

```
> my.ncp <- 9*3*var(c(9,9,10,12))/9
> 1-pf(qf(.95,3,32),3,32,my.ncp)
[1] 0.4655894
```

Another example: consider these hypothese for antibiotic binding fractions:

$$H_1: \mu_P = \mu + 3, \mu_T = \mu + 3, \mu_S = \mu - 6, \mu_E = \mu, \mu_C = \mu$$

Assume $\sigma = 3$ and we need to use $\alpha = \beta = 0.05$.

$$\gamma = n[(\frac{3}{3})^2 + (\frac{3}{3})^2 + (\frac{-6}{3})^2].$$

The following code should do the trick to calculate the necessary n

```
data one;
    do n=2 to 10;
        t=5; nu1=t-1; nu2=t*(n-1);
        sumtau2=3**2+3**2+(-6)**2;
        sigma2=9;
        ncp=n*sumtau2/sigma2;
        qf=finv(0.95,nu1,nu2);
        pf**probf(qf,nu1,nu2,ncp);
        power=1-pf;
        output;
    end;
run;
proc print;run;
```

```
